

# ***Compounds Containing Hydrogen (Acids and others)***

The names of molecular compounds containing hydrogen do not usually conform to the systematic nomenclature guidelines.

Many are called by the common, nonsystematic names or by names that do not indicate explicitly the number of H atoms present.

Examples (do not need to memorize all these, should know familiar ones like ammonia, water):

|                        |                  |
|------------------------|------------------|
| $\text{B}_2\text{H}_6$ | Diborane         |
| $\text{SiH}_4$         | Silane           |
| $\text{NH}_3$          | Ammonia          |
| $\text{PH}_3$          | Phosphine        |
| $\text{H}_2\text{O}$   | Water            |
| $\text{H}_2\text{S}$   | Hydrogen sulfide |

Use these Slides in Present Mode: on the practice slides the yellow boxes will disappear on click AFTER you have tried them. Please WRITE your answers, don't just think them. Writing or speaking completes the thinking process and promotes MUCH better learning.

## TECH SOLUTIONS

Look for this box throughout for alternative methods for those with slower internet etc. HINT: you can work in Offline mode after accessing once on a device (under file OR settings, depending on device) OR you can print the presentation. It has all the information and you can access the videos as needed when possible.

## Nomenclature Decision Flowchart

Video Description OR Skip to Written if preferred.

[Click HERE](#) to go to Slide with Video with Practice problems to try

## Acids

Acid: A compound in which one or more  $H^+$  ions are bonded to a negative ion.

acids

The name of an acid is based on the name of the negative ion part of the acid.

# Pneumonic for recalling the patterns you will learn

“My **ride** has **hydrolics**, I **ate** something **icky**, and **Sprite** is delici**ous**.”

# Acid-Forming Compounds

A compound must contain at least one *ionizable hydrogen atom* (forms an  $\text{H}^+$  ion in water) to be an acid upon dissolving.

| TABLE 5.7 |                      | Some Simple Acids |  |
|-----------|----------------------|-------------------|--|
| Formula   | Binary compound name | Acid name         |  |
| HF        | Hydrogen fluoride    | Hydrofluoric acid |  |
| HCl       | Hydrogen chloride    | Hydrochloric acid |  |
| HBr       | Hydrogen bromide     | Hydrobromic acid  |  |
| HI        | Hydrogen iodide      | Hydroiodic acid   |  |

# Naming Acids: Binary acids

- All acids start with H (e.g. HCl, H<sub>2</sub>SO<sub>4</sub>)
- TWO acid types exist: binary acids and oxyacids

Binary Acids: H + non-metal. E.g. HCl

Oxyacids: H + polyatomic ion. E.g. H<sub>2</sub>SO<sub>4</sub>

# ACIDS

- The two acid types have different naming rules.

Binary acids: naming depends on state → the molecules only have acidic properties when dissolved in water (aqueous state).

- If it's NOT aqueous it is named with ionic rules:  
hydrogen + non-metal name  
eg.  $\text{HCl}_{(g)}$  = hydrogen chloride
- If it IS aqueous: hydro + non-metal + ic acid  
 $\text{HCl}_{(aq)}$  = hydrochloric acid

# Pneumonic for recalling the patterns you will learn

My **ride** has **hydrolics** matches  
this naming pattern

# Practice (Present mode!- pay attention to state

## TECH SOLUTIONS

See slides at the end without the boxes. If printed off or working in offline mode, cover the answers and attempt to name.

# Naming Acids: Oxyacids

[Click to watch a video](#) on naming oxyacids with practice for simple acids as well. **The rules are written on the next slide for you.**

Practice questions are embedded. Please attempt them for your learning but they are NOT formally assessed.

## TECH SOLUTION

[Link to youtube video without embedded questions](#) for those with limited internet access. Use printable resources to practice.

# Naming Acids: Oxyacids

- 1) name the polyatomic ion
- 2) replace **ate** with **ic** OR **ite** with **ous**
- 3) change non-metal root for pronunciation (eg sulphuric is nicer to say than sulphic)
- 4) add “acid” to the name

E.g.  $\text{H}_2\text{SO}_3 \rightarrow$  **follow steps #1-4 above:**

- 1) sulphite,
- 2) sulphous,
- 3) sulphurous,
- 4) sulphurous acid

**Final name** 

# Pneumonic for recalling the patterns you will learn

I **ate** something **icky**, and **Sprite** is  
delici**ous**.”

This part of the pneumonic  
matches these naming rules

# Rule Summary & Exceptions

## Acids

-Compound where one or more  $H^+$  ions are bonded to a negative ion

### Binary Acids

-Hydrogen + Nonmetal

Binary compound name  $\rightarrow$  ide

Ex.  $HF_{(g)}$  Hydrogen fluoride

- Acid name

ide  $\rightarrow$  Hydro\_\_\_\_-ic acid

Ex.  $HF_{(aq)}$  = Hydrofluoric acid

### Oxyacids

- H + polyatomic ion

ate  $\rightarrow$  -ic acid

Ex.  $H_2CO_3$  = Carbonic acid

ite  $\rightarrow$  -ous acid

Ex.  $HNO_2$  = Nitroous acid

| <u>Negative Ions</u> |          |
|----------------------|----------|
| Fluoride             | $F^-$    |
| Chloride             | $Cl^-$   |
| Bromide              | $Br^-$   |
| Iodide               | $I^-$    |
| Oxide                | $O^{2-}$ |
| Sulfide              | $S^{2-}$ |
| Nitride              | $N^{3-}$ |
| Phosphide            | $P^{3-}$ |

| <u>Polyatomic Ions</u> |             |
|------------------------|-------------|
| Carbonate              | $CO_3^{2-}$ |
| Chromite               | $CrO_2^-$   |
| Hypochlorite           | $ClO^-$     |
| Nitrate                | $NO_3^-$    |
| Nitrite                | $NO_2^-$    |
| Permanganate           | $MnO_4^-$   |
| Phosphate              | $PO_4^{3-}$ |
| Phosphite              | $PO_3^{3-}$ |
| Sulfate                | $SO_4^{2-}$ |
| Sulfite                | $SO_3^{2-}$ |

### Important exceptions(polyatomic ion):

-phosphate= phosphoric acid

-Phosphite=Phosphorous acid

-Sulfate=Sulfuric acid

-Sulfite= Sulfurous acid

# Practice (in present mode, boxes disappear on click after you try them.)

1. nitrous acid

2. phosphoric acid

3.  $\text{HClO}_{(\text{aq})}$

4.  $\text{H}_2\text{CO}_{3(\text{aq})}$

## TECH SOLUTIONS

See slides at the end without the boxes. If printed off or working in offline mode, cover the answers and attempt to name.

# Special Nomenclature Case - Hydrates

A hydrate is an ionic compound that has water molecules incorporated into their solid structures.  
NOTE: these are NOT acids. ANY ionic compound that does this with water is a hydrate.

Writing the formula: name of ionic compound · #H<sub>2</sub>O

Pg 89

The Hydrate of copper sulfate is the pentahydrate, and the anhydrous copper sulfate will absorb water to form the Hydrate.

$\text{CuSO}_4 \cdot 5 \text{H}_2\text{O}$

**Copper(II)sulfate pentahydrate**

Olmsted Williams

## Special case → Hydrates

A **hydrate** is a compound that has a specific number of water molecules trapped within its solid structure. The water trapped in the solid crystal is called the **water of hydration**.

For example, in its normal state, copper(II) sulfate has five water molecules associated with it. Name compound as usual. Add hydrate with the prefix indicating the number of water molecules.

*Systematic name: copper(II) sulfate pentahydrate*

*Formula:  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$*

Some other hydrates are

*Note the dot between the main compound and associated water molecules.*

# Optional 3 minute video on Hydrates

[Click here](#)

{FYI, I can't embed the ones with questions  
inserted into Slides)

## Hydrates - Anhydrous

When the water molecules are driven off by heating, the resulting compound,  $\text{CuSO}_4$ , is sometimes called **anhydrous copper(II) sulfate**.

*Anhydrous* means the compound no longer has water molecules associated with it.

This is why we use a dot in the formula because the heating of the compound removes the ASSOCIATED water molecules but does not alter the salt formula OR properties. The water is NOT bound to or part of the salt.

# Watch a Hydrate Expt (<3mins)

{Not req'd if you have tech challenges but good to watch if possible}

# RECALL: Bases & Naming

Reminder: A **base** can be defined as a substance that yields hydroxide ions ( $\text{OH}^-$ ) when dissolved in water. There are no special naming rules for bases.

sodium hydroxide

potassium hydroxide

barium hydroxide

## For Interest : Familiar Compounds

| TABLE 5.11 Common and Systematic Names of Some Familiar Inorganic Compounds |                             |                                |
|---|-----------------------------|--------------------------------|
| Formula   | Common name                 | Systematic name                |
| H <sub>2</sub> O  | Water                       | Dihydrogen monoxide            |
| NH <sub>3</sub>   | Ammonia                     | Trihydrogen nitride            |
| CO <sub>2</sub>   | Dry ice                     | Solid carbon dioxide           |
| NaCl  | Salt                        | Sodium chloride                |
| N <sub>2</sub> O  | Nitrous oxide, laughing gas | Dinitrogen monoxide            |
| CaCO <sub>3</sub>   | Marble, chalk, limestone    | Calcium carbonate              |
| NaHCO <sub>3</sub>  | Baking soda                 | Sodium hydrogen carbonate      |
| MgSO <sub>4</sub> · 7H <sub>2</sub> O                                       | Epsom salt                  | Magnesium sulfate heptahydrate |
| Mg(OH) <sub>2</sub>   | Milk of magnesia            | Magnesium hydroxide            |

If you are feeling confident, you CAN STOP HERE and continue to the nomenclature sheets practice on the unit plan. Remaining slides provide more Worked examples and another video for those that need further assistance.

## Worked Example 5.10

Name the following species: (a)  $\text{BrO}_4^-$ , (b)  $\text{HCO}_3^-$ , and (c)  $\text{H}_2\text{CO}_3$ .

**Strategy** Each species is either an oxyanion or an oxyacid. Identify the “reference ion” (the one with the *-ate* ending) for each, and apply the rules to determine appropriate names.

**Solution** (a)  $\text{BrO}_4^-$  has one more O atom than the bromate ion ( $\text{BrO}_3^-$ ), so  $\text{BrO}_4^-$  is the *perbromate* ion.

(b)  $\text{CO}_3^{2-}$  is the carbonate ion. Because  $\text{HCO}_3^-$  has one ionizable hydrogen atom, it is called the *hydrogen carbonate ion*.

(c) With two ionizable hydrogen atoms and no charge on the compound,  $\text{H}_2\text{CO}_3$  is *carbonic acid*.

## Worked Example 5.11

Determine the formula of sulfurous acid.

**Strategy** The *-ous* ending in the name of an acid indicates that the acid is derived from an oxyanion ending in *-ite*. The oxyanion must be sulfite,  $\text{SO}_3^{2-}$ , so add enough hydrogen ions to make a neutral formula.

**Solution** The formula of sulfurous acid is  $\text{H}_2\text{SO}_3$ .

**Think About It** Remembering all these names and formulas is greatly facilitated by memorizing the common ions that end in *-ate*.

# Naming acids practice

## Naming Acids Practice Problems

negative ion

-ide

acid  
hydro\_\_\_\_\_ic acid

example  
chloride hydrochloric acid

-ate

-ic acid

nitrate nitric acid

-ite

-ous acid
